

Beta Squeeze Using a New Matching Routine in MadX

Work outline and first results

Introduction

Algorithm

Introduction

The dipole first layout for the $.25\text{m}\beta^*$ LHC introduces new difficulties for the matching of the insertion region:

- ▶ β^* peak is 18km pushing the limit on the quadrupole strengths;
- ▶ the dispersion has to be different from zero before entering the triplets, giving to Q4-Q7 an additional task.

Finding a continuous path between the collision and the injection optics gets more difficult.

It needs to take the full advantage to have

- ▶ 20 variables (Q4-Q13 RL) for
- ▶ 14 constraints ($\beta_x \beta_y \alpha_x \alpha_y d_x dp_x$ right and left and $\mu_x \mu_y$)

MadX Matching Routines

Madx provides two main matching routines:

- ▶ lmdif: fast but limited to problems where $c \leq v$
- ▶ simplex: slow and not suited for constrained problems (solutions get far from the starting point)

A new matching routines has been developed in order to be:

- ▶ fast;
- ▶ suited for constrained problems (find the closest solution from the starting point);
- ▶ suited for problems where $v \geq c$;

After some testing the routine shows good results if:

- ▶ it exists a good solution with close constraints
- ▶ the problem is such that $v > c$ (for $v = c$ lmdif perform more reliable)

Algorithm

The algorithm is based on a simple implementation of the Newton-Raphson method.

A matching problem can be written as:

$$\mathbf{c} = \mathbf{f}(\mathbf{v})$$

where \mathbf{c} is vector of the c constraints, \mathbf{v} is vector of the v variables and \mathbf{f} is vector field representing the optics.

If $\mathbf{c}_0 = \mathbf{f}(\mathbf{v}_0)$ is a good solution for \mathbf{c}_0 close to \mathbf{c} then the vector field can be approximated with :

$$\mathbf{c} = \mathbf{c}_0 + \frac{D\mathbf{f}}{D\mathbf{v}}(\mathbf{v}_0)\delta\mathbf{v} + O(|\delta\mathbf{v}|^2)$$

and the solution found by iterations using :

$$\mathbf{v} = \mathbf{v}_0 + \delta\mathbf{v} \quad \frac{D\mathbf{f}}{D\mathbf{v}} = \mathbf{J} \quad \delta\mathbf{v} = \mathbf{J}^{-1}(\mathbf{c} - \mathbf{c}_0)$$

\mathbf{J} has c rows and v columns and if $v > c$ the problem can be solved such that $|\delta\mathbf{v}|$ be minimum with LQ decomposition.

Try 1

- ▶ Increase of β^* of 10%
- ▶ No additional constraints

Try 2

- ▶ Increase of β^* of 10%
- ▶ Slope of Q4 left and right and Q9 left fixed
- ▶ beta max for Q6 Q8 left and right set to be half of beta max in the triplet
