

Intermediate steps for β squeeze in IP 8

W. Herr

Steps in $\Delta \beta^*$ for squeeze

- Present β^* squeeze in IP8:
 - 10 m (nominal) to 2 m (low intensity)
 - From Malika: intermediate steps every 0.5 m
- Can we go to larger steps (e.g. 1 m) ?
- Interpolate between two points and compare with exact optics
- Check possible β -beating and optics mismatch

Example: β squeeze (β_x , beam 1)

β squeeze

β_y interpolation

➤ β_y 3m and 2m interpolated to 2.5m

β_y interpolation

➤ β_y in ARC, 3m and 2m interpolated to 2.5m

β_x interpolation

➤ β_x 4m and 2m interpolated to 3.0m

β_y interpolation

➤ β_y 4m and 2m interpolated to 3m

β_y interpolation

➤ β_y in ARC, 4m and 2m interpolated to 3.0m

β_x interpolation

➤ β_x 3m and 4m interpolated to 3.5m

β_y interpolation

➤ β_y 3m and 4m interpolated to 3.5m

β_y interpolation

➤ β_y 6m and 7m interpolated to 6.5m

β_x interpolation

Interpolation	β -beating $\left(\frac{\beta_t - \beta_i}{\beta_t}\right)_{max}$	$\Delta Q'$
2,3 → 2.5m	5.0% (local)	≈ 0.2
3,4 → 3.5m	4.5%	≈ 0.1
4,5 → 4.5m	1.0%	≈ 0.03
6,7 → 6.5m	7.0% (local)	≈ 0.07
7,8 → 7.5m	1.0%	≈ 0.02
9,10 → 9.5m	0.5%	≈ 0.002
2,4 → 3.0m	10% (in arc !)	≈ 0.5
8,10 → 9.0m	3.5%	≈ 0.02

Summary

- For steps of $\Delta\beta^* = 1\text{m}$:
 - β -beating small for $\beta^* \geq 4\text{ m}$
 - Optics changes (tune, chromaticity) very small
- $\Delta\beta^* = 1\text{ m}$ o.k
- Maybe for last steps (and $6\text{m} \rightarrow 7\text{m}$) $\Delta\beta^* = 0.5\text{ m}$
- Other issues: crossing schemes during pre-/squeeze
