- Orbit and dispersion measurements on MD2 (june 2007)
- Orbits measurements at the transition with steering and non-equilibrated Triplets

GammaJump Quadrupole Currents in the PS

Quadrupoles placed in doublets and triplets magnets

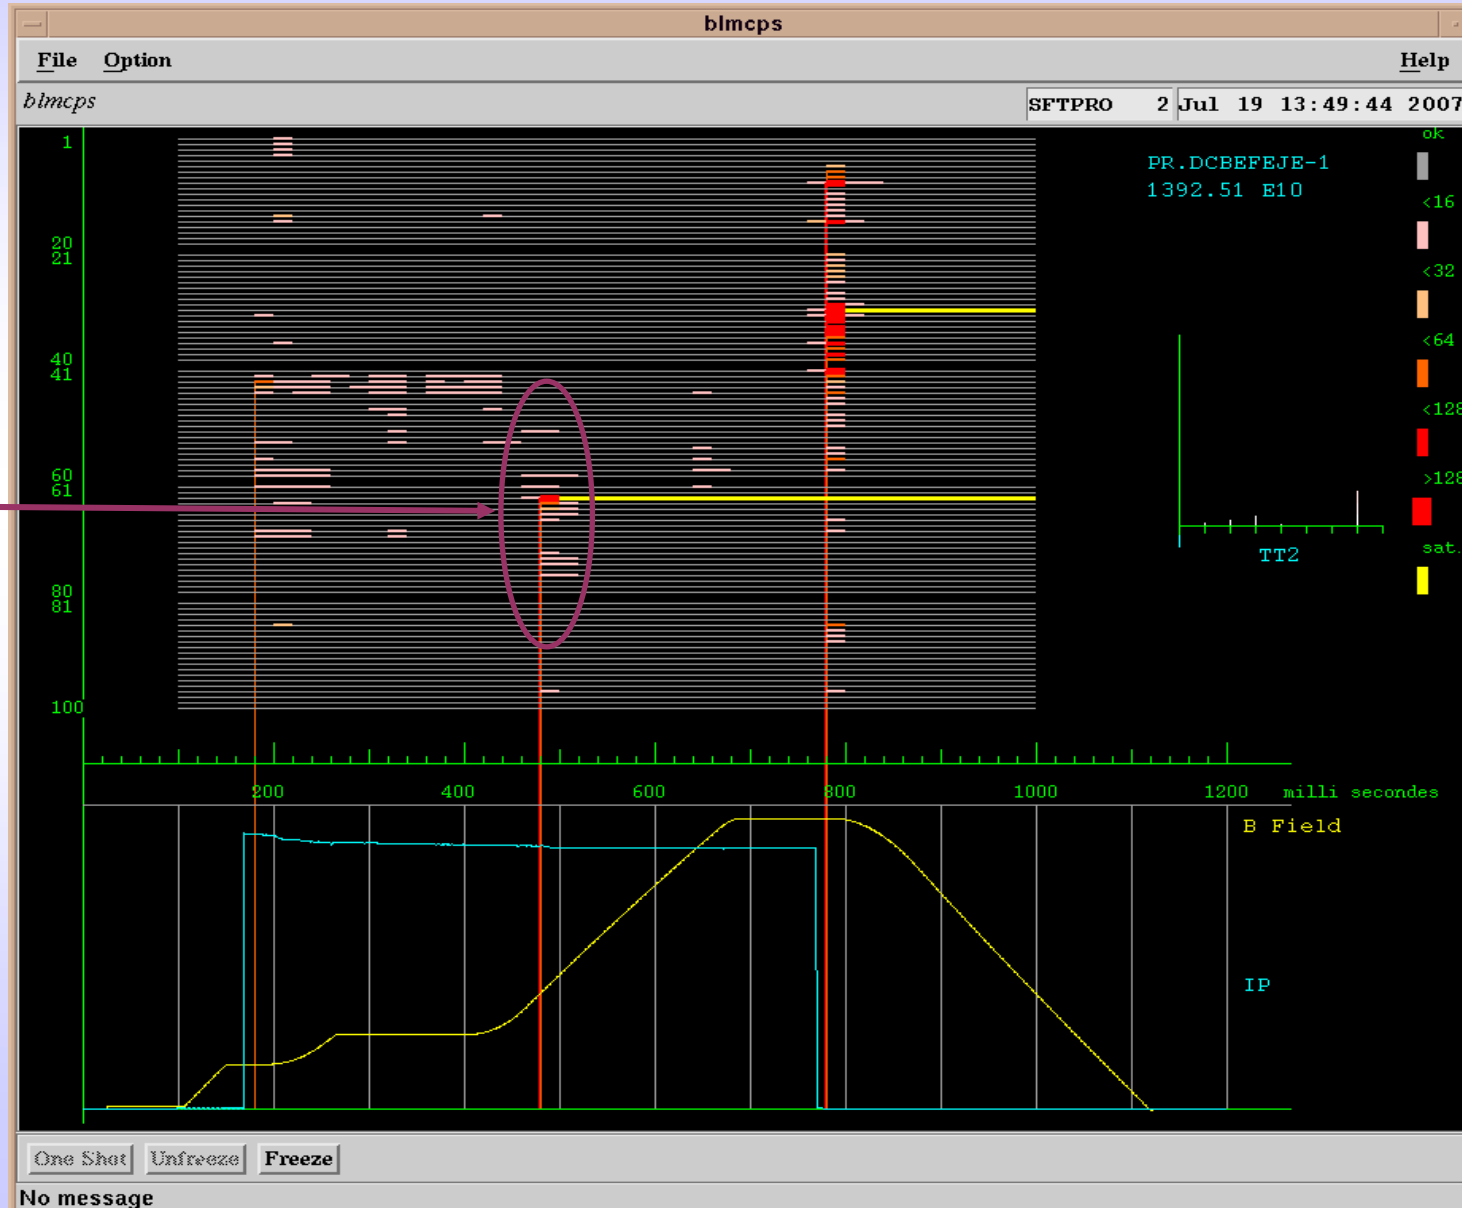

Motivations

2 Juillet
2007
SFTPRO

Transition

About 1-2% of the beam is lost at transition without any correction

This corresponds to 10-20 e10, roughly a complete EAST cycle

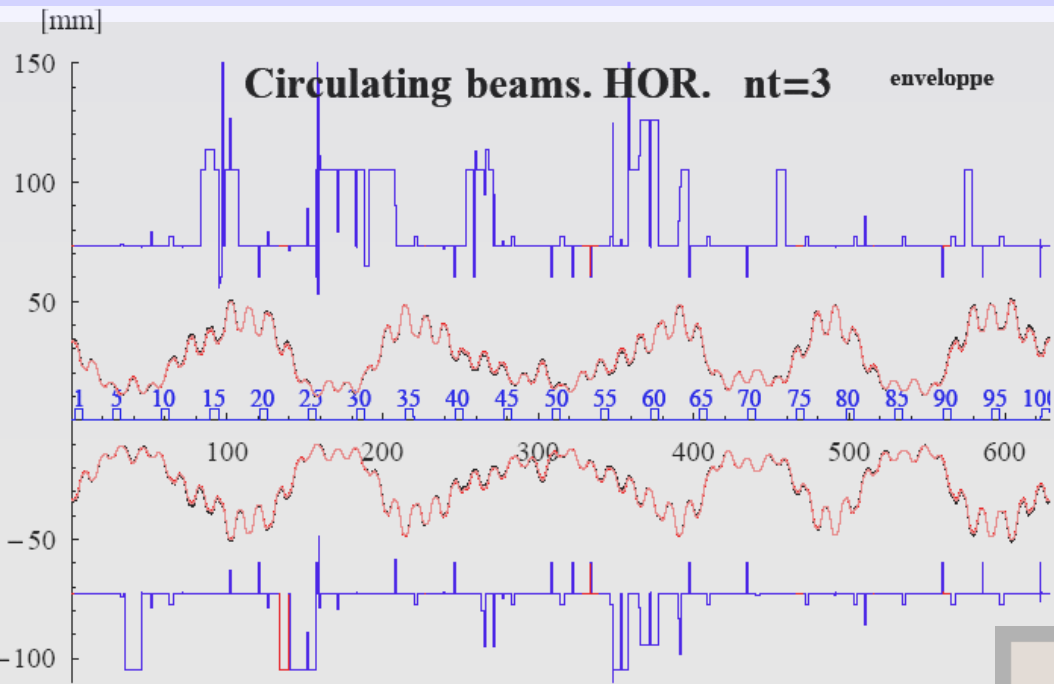

Motivations

Last year, we demonstrated the causes the beam losses at the transition :

- ✘ Beam envelope blow-up, we can control by changing unbalanced triplet currents
- ✘ Orbit distortion at the transition

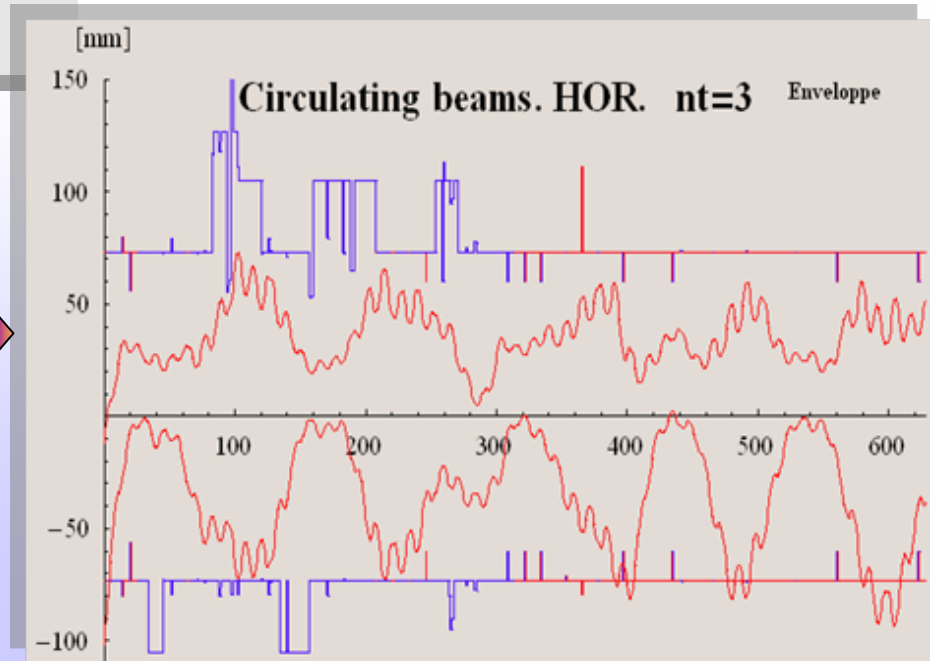

Blow-up of the envelope at the transition

Beam envelope at the transition

losses probably reduced if no orbit distortion

Beam losses in SS63 measured and confirmed by MAD simulation.
Here envelope + measured orbit

Motivation: beam envelope by the use of unbalanced triplets currents

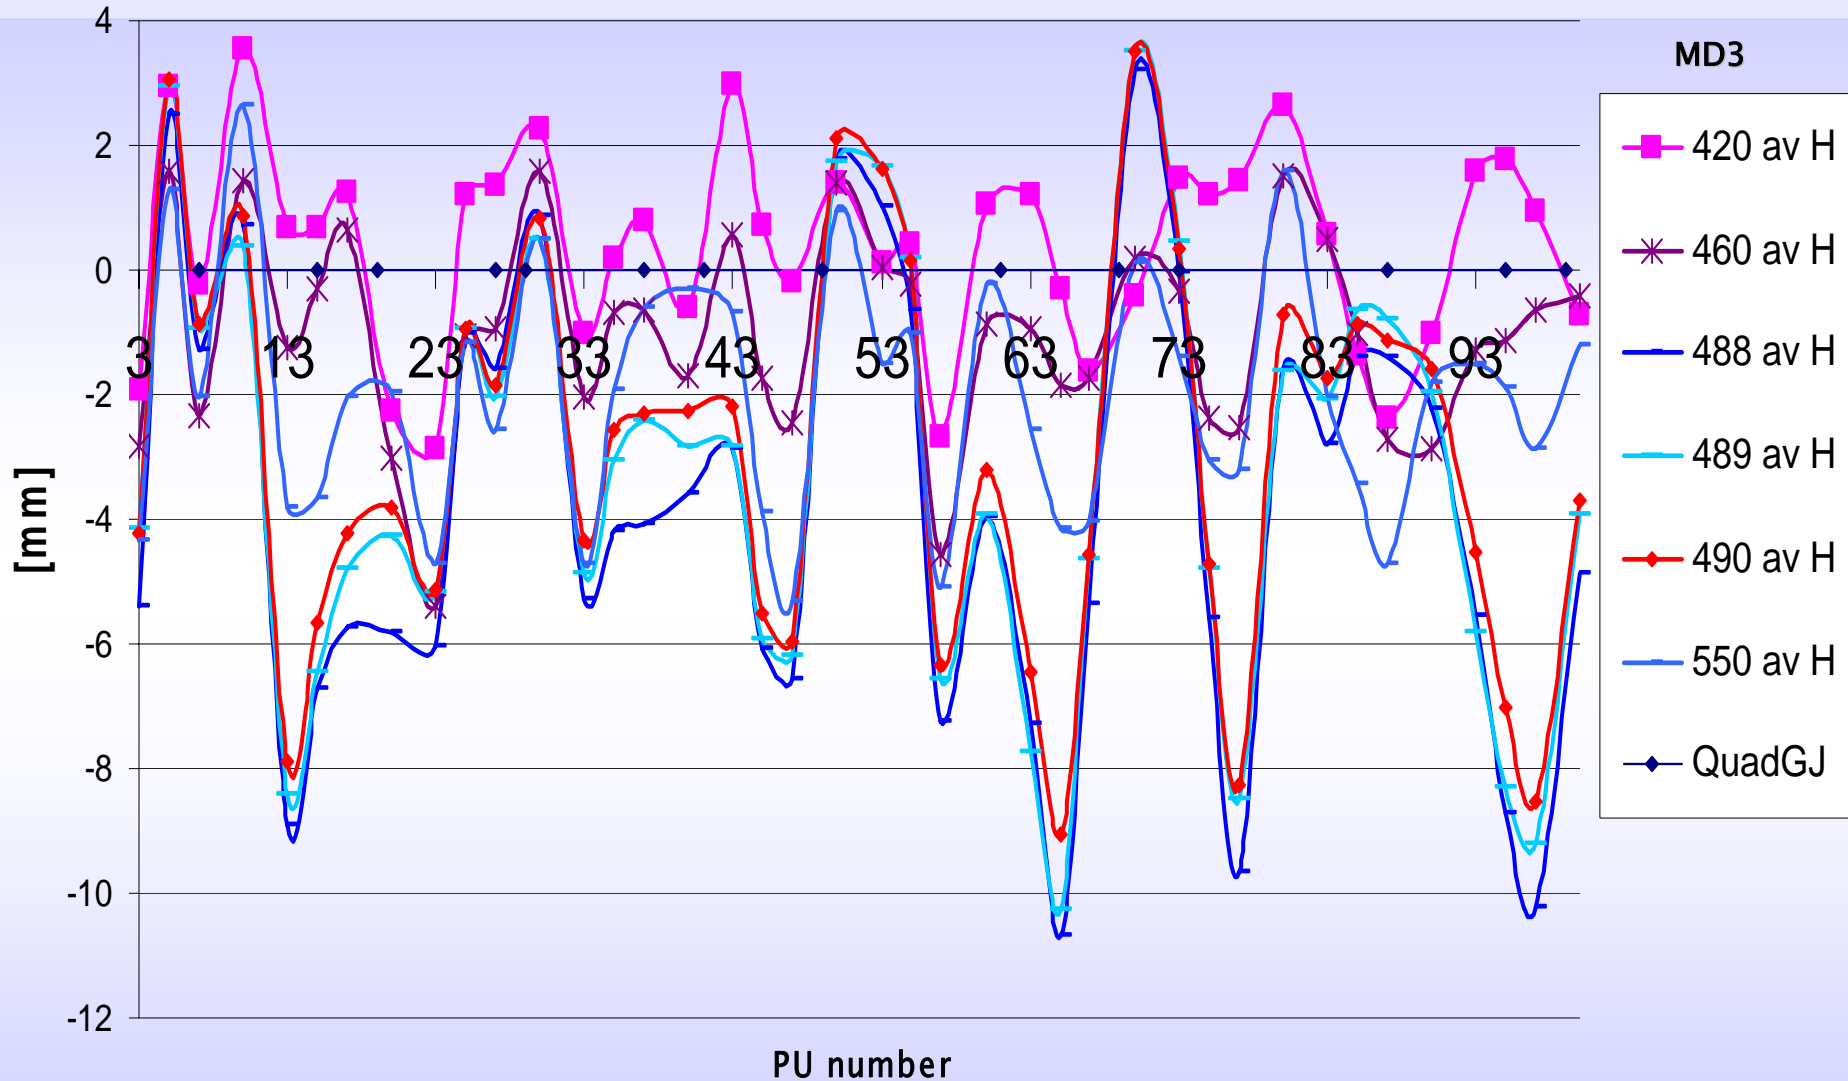

rouge: machine normal – rose: +30% doublets et triplets - vert: +30% triplet

Motivations

Last year, we demonstrated the causes the beam losses at the transition :

- ✘ Beam envelope blow-up, we can control by changing unbalanced triplet currents**
- ✘ Orbit distortion at the transition**

Orbit distortion in the horizontal plane

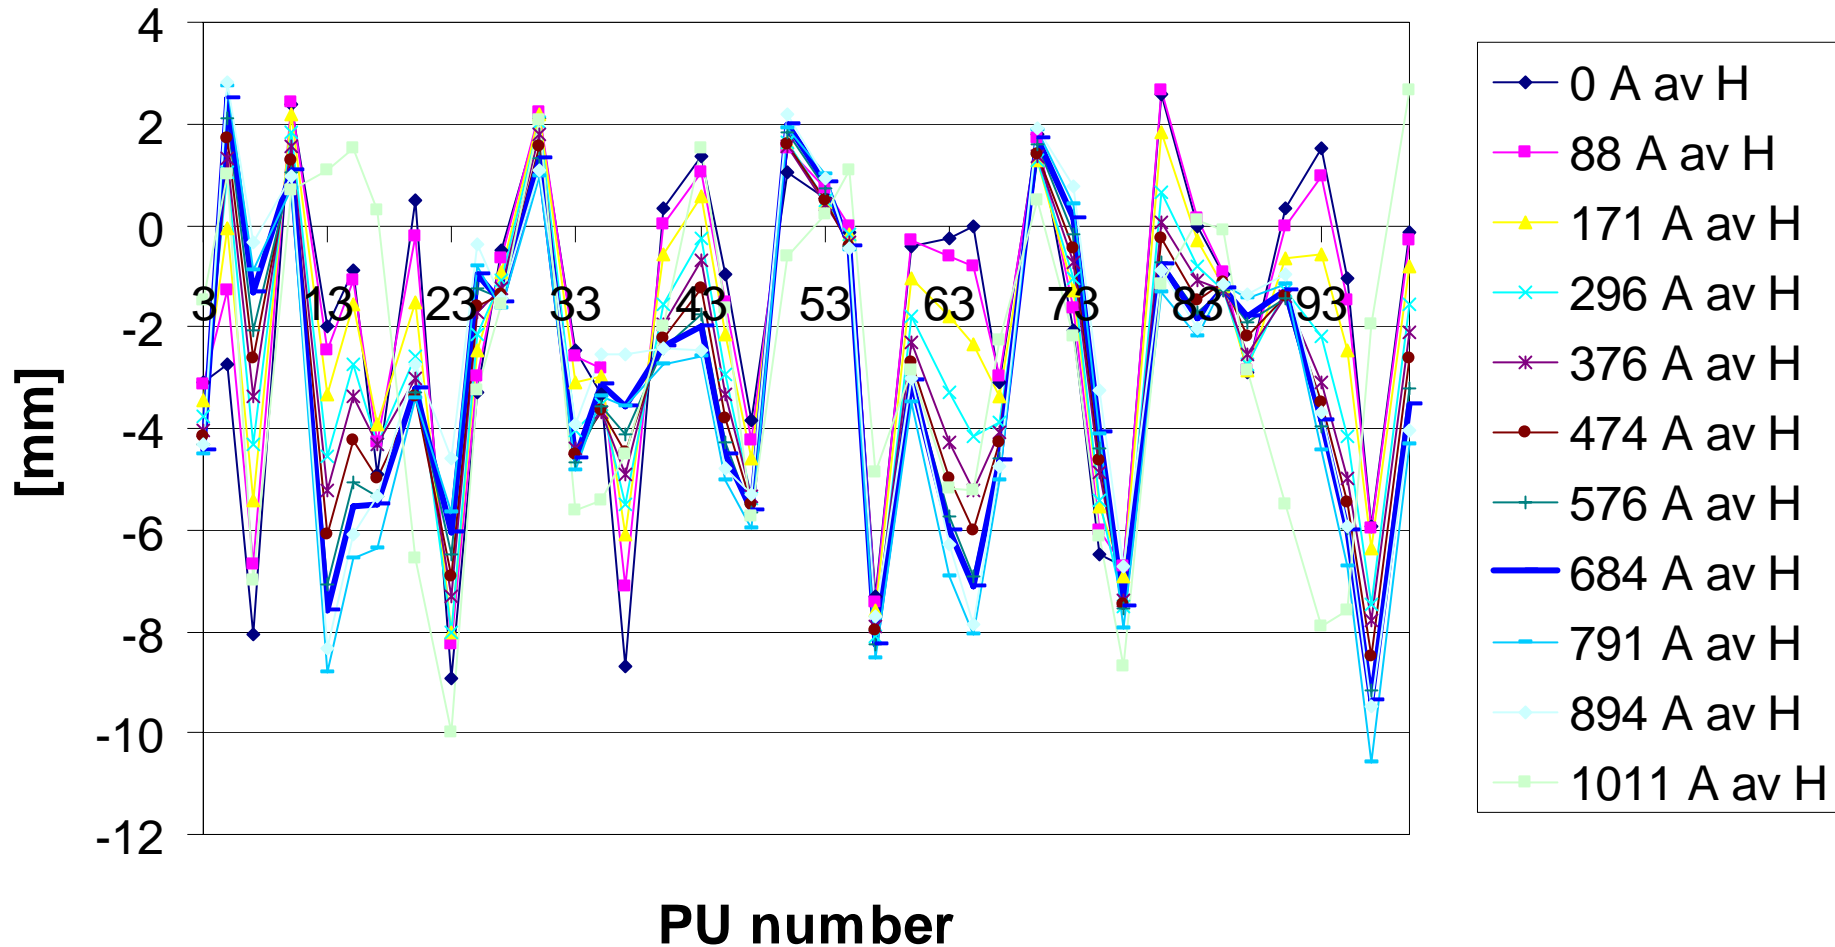

Orbit distortion measured in the horizontal plane in june 2006 at the transition
probably due to GammaJump elements

Causes: quadrupoles misalignments ?

Orbit measurements at the transition by varying the doublet magnets

Measured H orbits near transition

Questions ?

The main cause of Orbit Distortion problem is:

- a related to the beam control (radial or phase loop)?
- a physics problem ? Due to quadrupole misalignments?
- Both ?

The latest could be checked by simulation with MAD

The quadrupoles have been realigned during this Shutdown

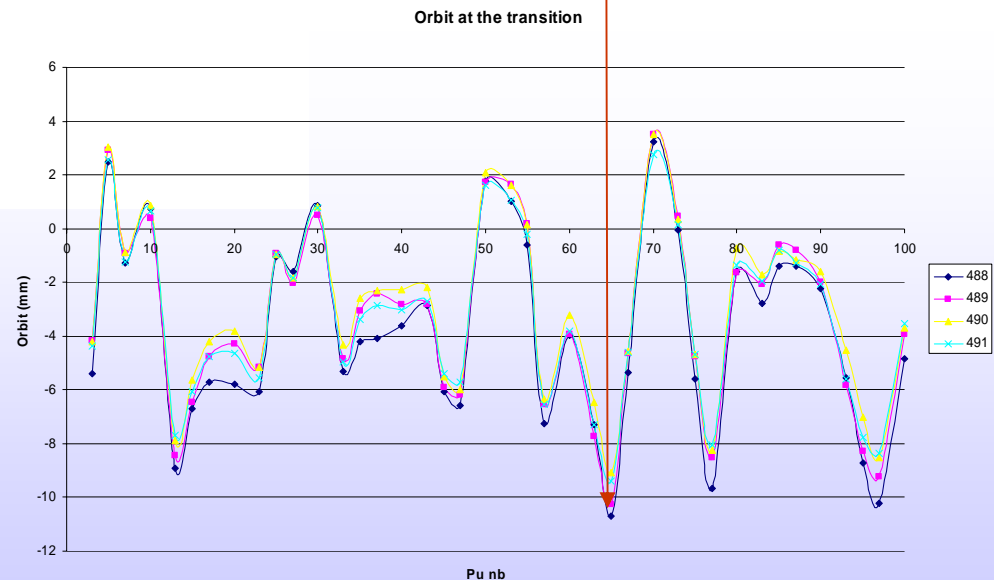

| N° SECTION DROITE | QUADRUPOLE | enmm | | enmm | | mid TILT |
|-------------------|------------|--------|----------|--------|--------|----------|

Orbit meas with Elias and Rende
Quads alignements from T. Dobers

Results of the PS orbit simulation with GJ quadrupole misalignments

The orbit due to the quadrupole misalignments is out of phase by a **factor π** with respect to the measured orbit

The quadrupole misalignments are not a sufficient explanation to find the same order of magnitude ($x[\text{Pu}63] = -10 \text{ mm}$ at the transition instead of 0.5 mm calculated by simulation)

First conclusions...

- The GJ quadrupole misalignments are not the main causes of the orbit distortion, they have a weak influence (maximum around 1 mm).

- It is not possible to reproduce the “real” orbit by simulation

NEED to introduce more errors in MADX PS model IF THE ORBIT DISTORTION IS NOT A CONTROL PROBLEM.

- Next, orbit and dispersion measurements to find out the cause (dispersion growing ? Energy mismatch ? Problem of beam control ?)

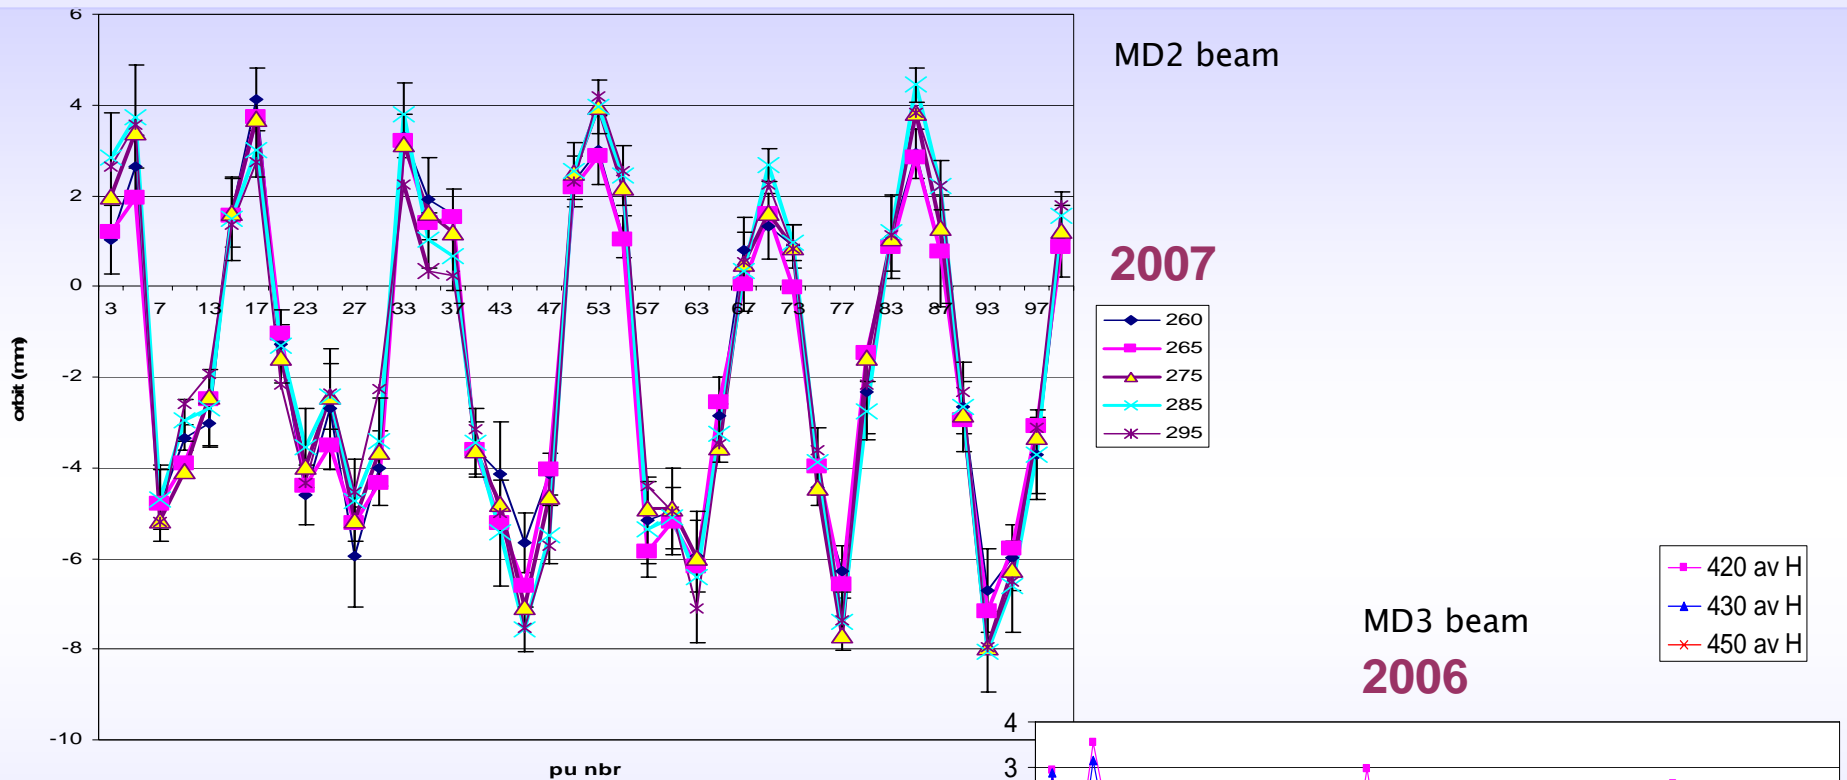

MD 18 of June 2007

**Orbits and Dispersion measurements
at the transition**

Contents of the MD

- ✘ Orbit measurements with the nominal values of GJ quadrupoles.
- ✘ Dispersion measurements by applying a radial steering to the beam – These measurements have been made to confirm or not the MADX model.
- ✘ Tune measurements for the MADX model
- ✘ Orbit measurements by switching off some GJ quadrupoles

Beginning of the GJ magnetic cycle: measured orbit in the horizontal plane

- No triplet magnet effects, seems the magnets are well aligned, compared to the orbit from 2006
- Could be also an effect of the beam

Measured orbit in the horizontal plane: at the transition

Mean Radial Position of the beam

The radial position changed suddenly with phase inversion at the transition

Orbit Measurements without PFW and/or Quadrupoles

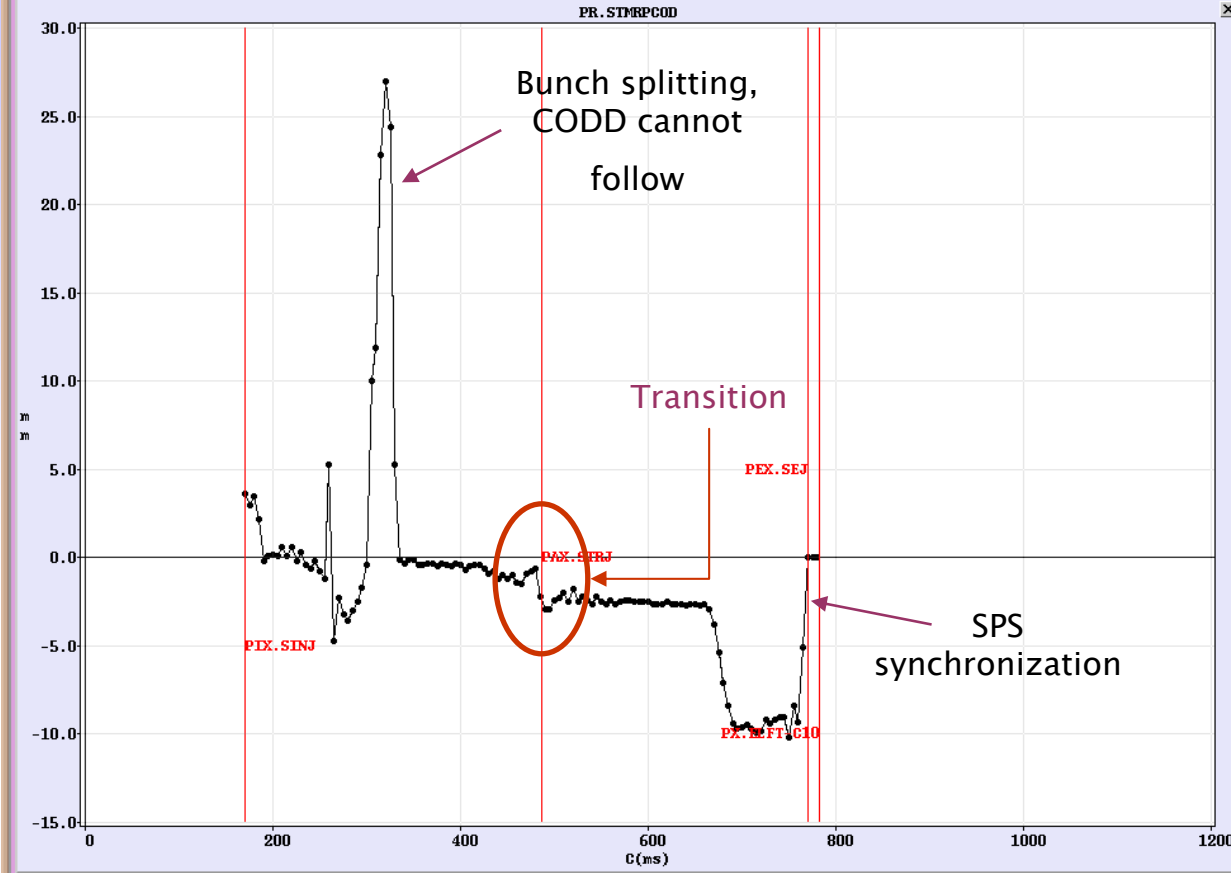

No orbit distortion if No GJ quadrupoles

MRP without PFW and/or Quadrupoles

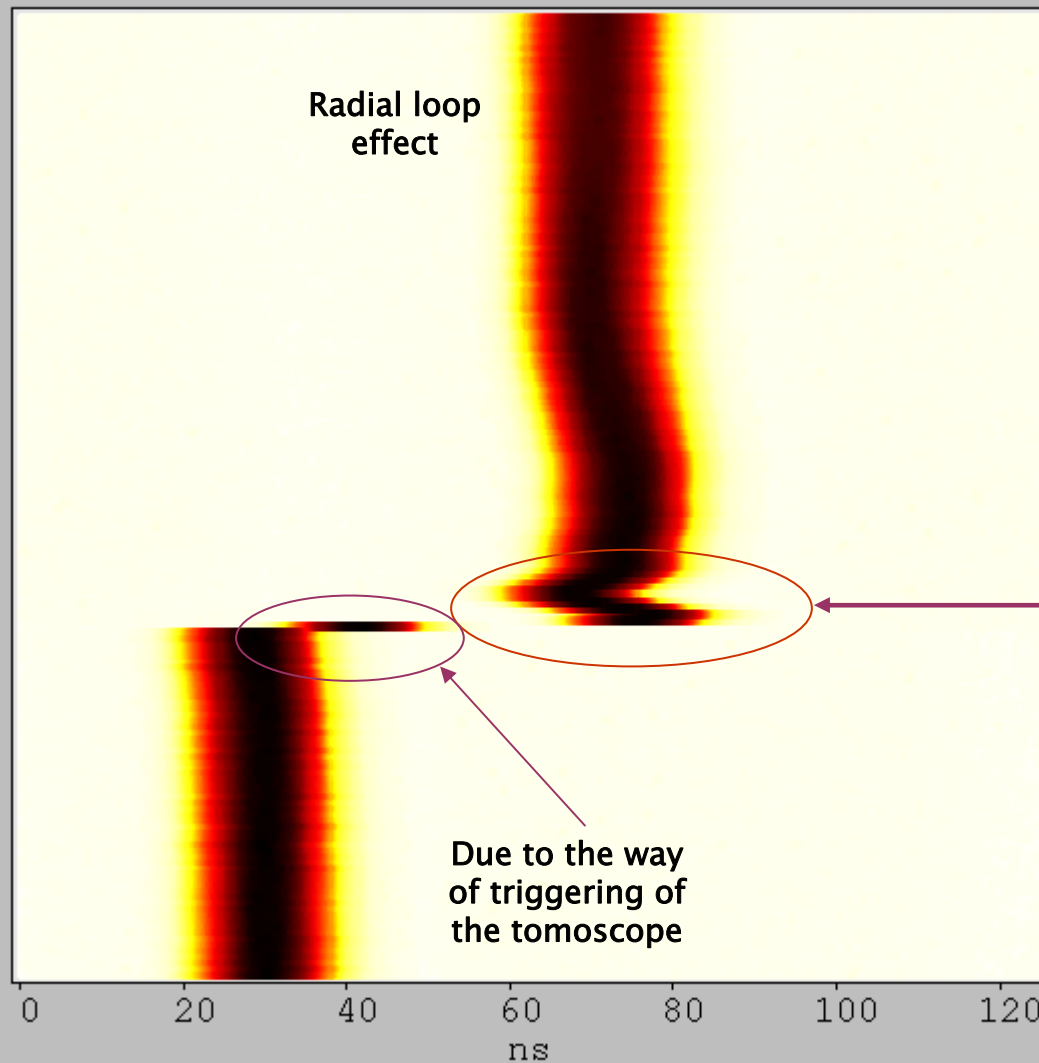

MRP calculated with the 40 PU

SFTPRO 19 July 2007

MRP calculated with the PU 22-51-96

C Timing 486

Measured Dispersion vs simulated dispersion

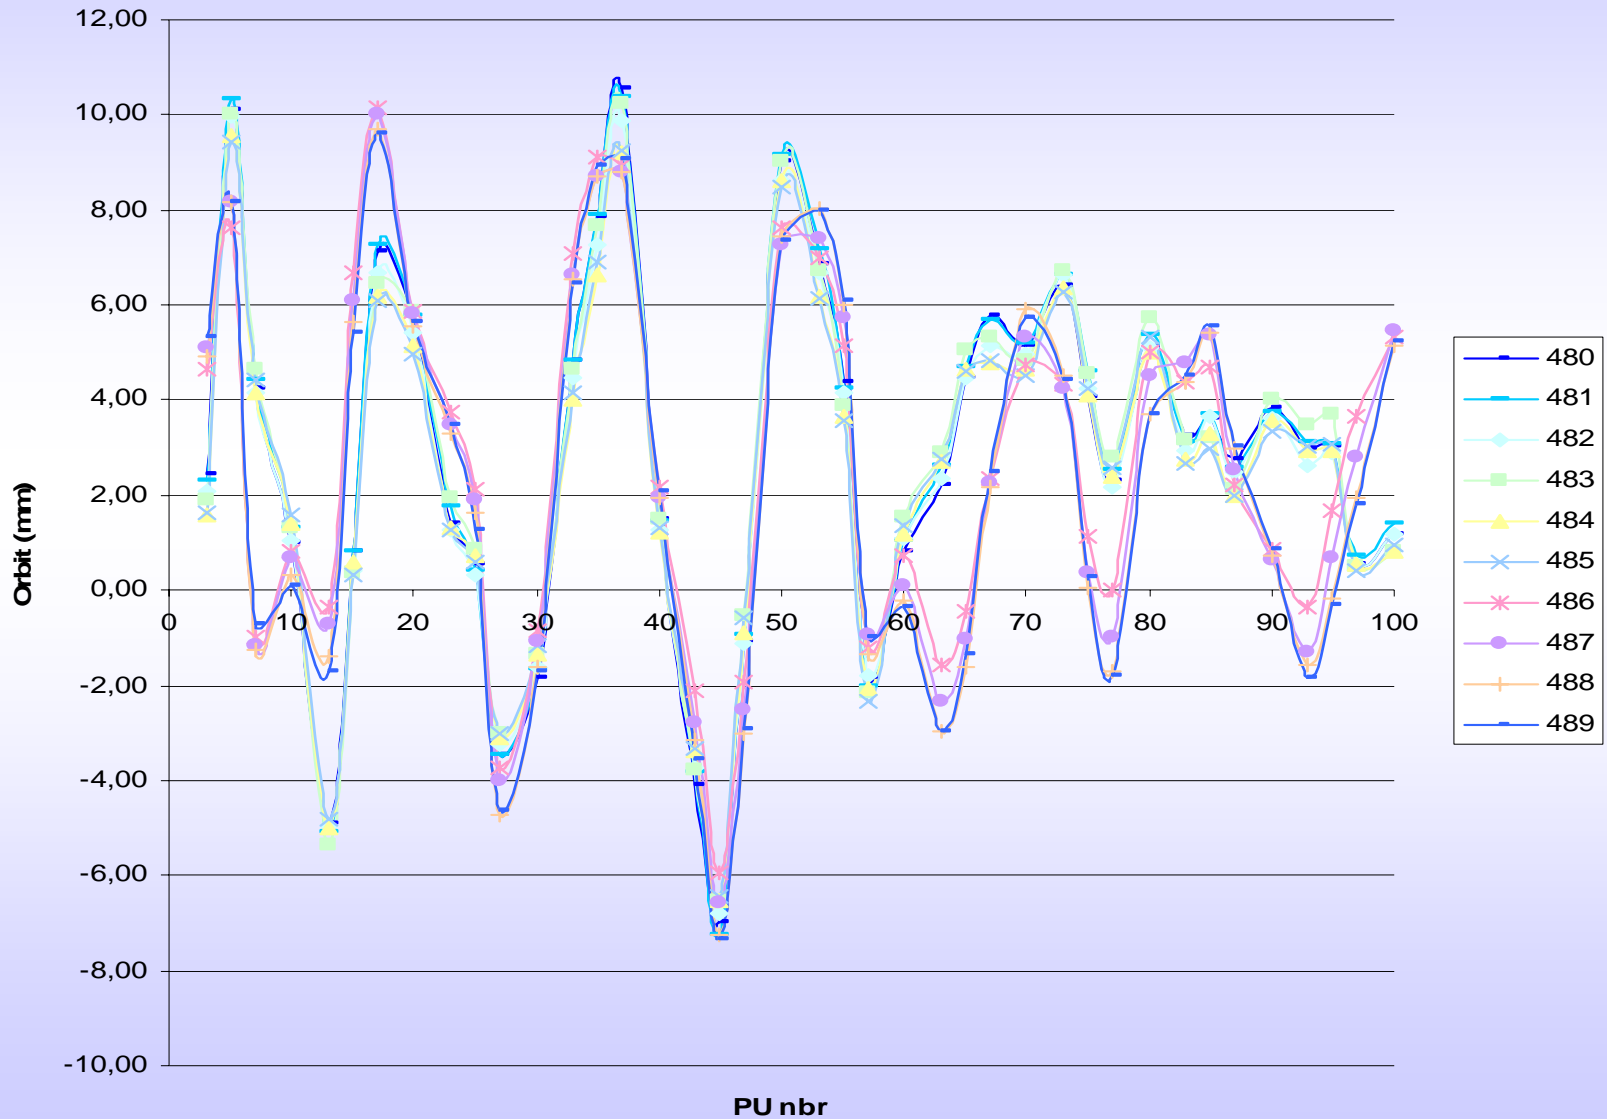

**Orbit measurements at the transition
with steering and non-equilibrated
Triplets**

How to correct the beam at the transition ?

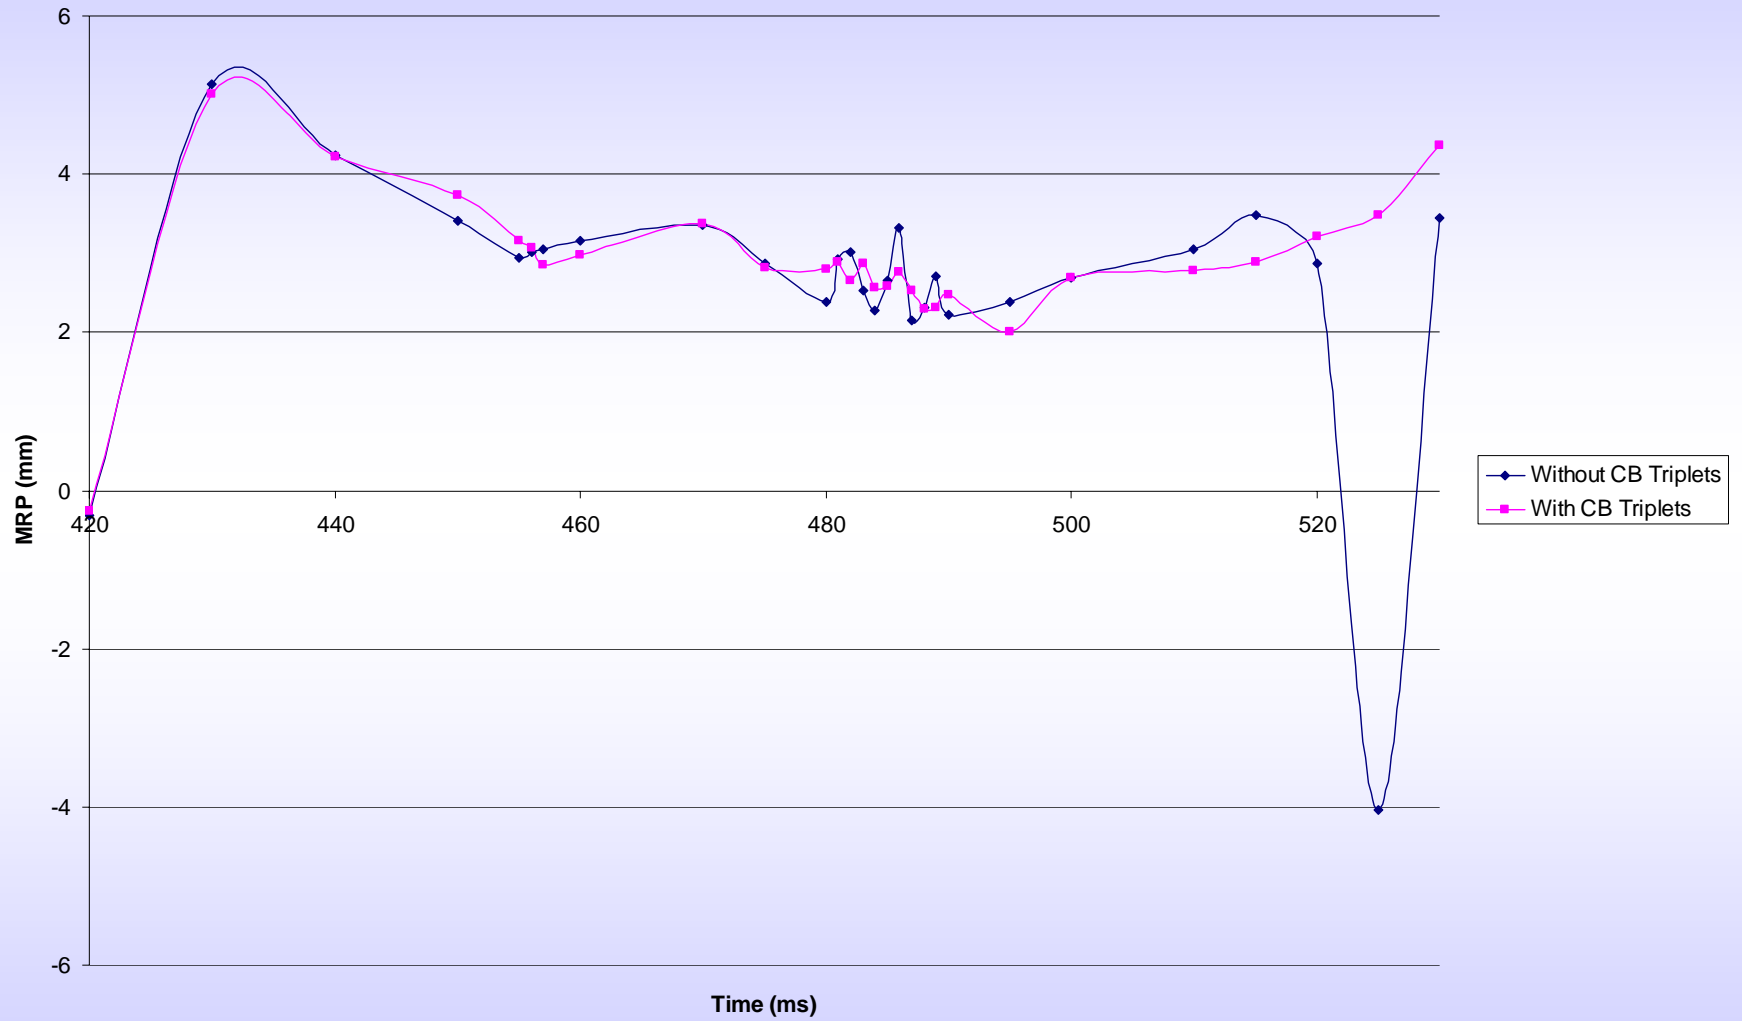

- ✘ Radial steering of 3.50 mm at the injection to compensate the MRP jump
- ✘ Unbalanced triplets : 0.8 of the nominal value in part A and 0.9 in part B

Orbit with the radial steering and nominal triplet value

MRP with the steering

Phase jump with the oscilloscope

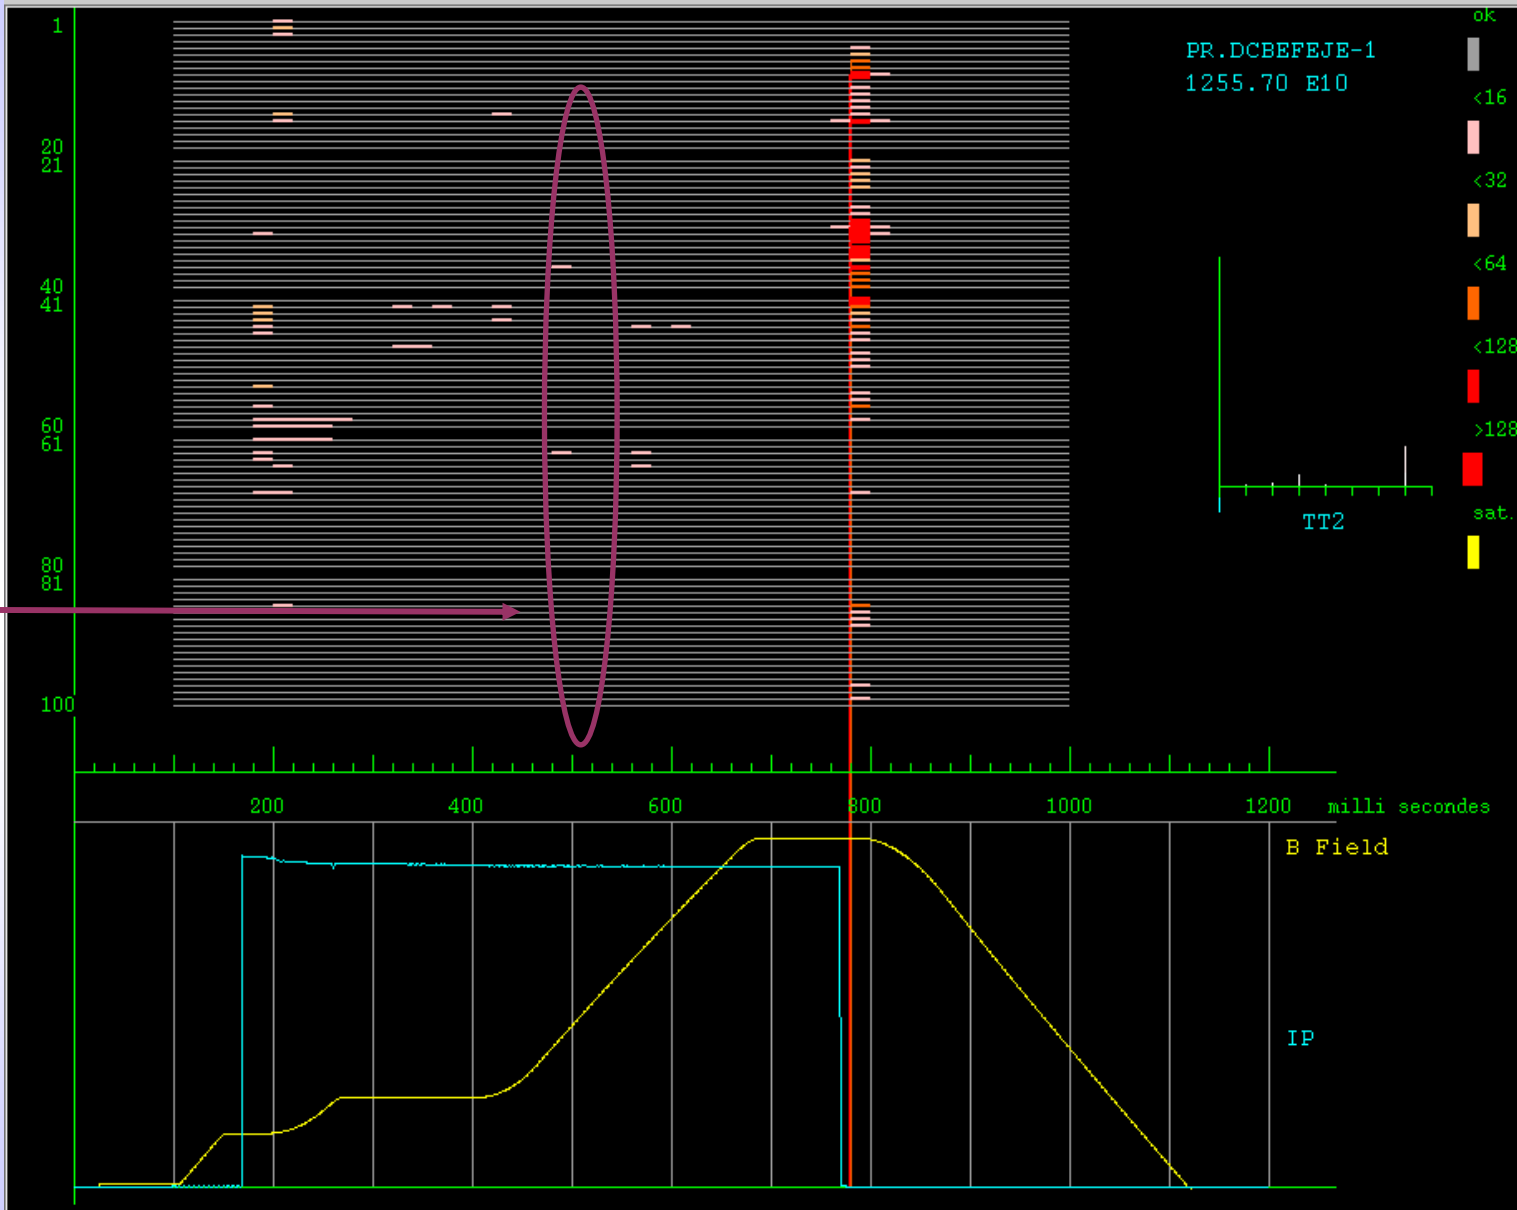

Beam more intense

There used to be no large phase oscillation for half of the TOF beam loading on the cavities

SFTPRO
19 July 2007

Transition

0.2% Losses !!

Conclusions

Orbit distortion problem : phase and radial loop control problem

- ✘ With the radial steering and/or the unbalanced triplet magnets, reduction of the beam losses at the transition
- ✘ Some losses appear in SS35 for exemple, but it is explained by the MADX model

What to do next

- ✘ Orbit measurements in detail with the radial loop gain OFF
- ✘ Orbit correction at the transition with MICADO
